1. Introduction

Usability testing was conducted for the SafeRide mobile application prototype to evaluate the ease of use, clarity, navigation, and overall user experience of the designed screens.

The testing focused on the main ride-booking journey and the emergency SOS flow. Two teammates were asked to interact with the clickable Figma prototype and complete predefined tasks without being given step-by-step instructions.

The purpose was to identify usability problems before finalizing and submitting the Week 2 design.

2. Testing Participants

Participant	Role	Testing Focus
Participant 1	Iqra Tahir	Ride booking and driver verification
Participant 2	Arnib Butt	Live tracking and SOS emergency flow

The participants were selected from the project team because they were familiar with the project but had not been responsible for designing every screen they tested.

3. Testing Method

The usability test was performed using the clickable Figma prototype.

Participants were given realistic scenarios and asked to complete tasks independently. The team lead observed their interactions and recorded difficulties, confusion, and suggestions.

The following aspects were evaluated:

- Ease of navigation
- Clarity of buttons and actions
- Understanding of driver information
- Visibility of the AI Safety Score

- Ease of finding the SOS button
 - Understanding of the SOS process
 - Overall visual clarity
 - Consistency between screens
-

4. Usability Test Tasks

Task 1 – Start a Ride

Scenario

"You want to book a SafeRide. Starting from the Welcome screen, log in and select a driver."

Expected Flow

Welcome → Login → Home/Rides → Driver Selection → Driver Verification

Observation

The participant was able to understand the main navigation and identify the Get Started and Login actions. The driver cards on the Home screen provided enough information to compare drivers.

Result

Successful

Task 2 – Check Driver Safety

Scenario

"Before booking the ride, check whether the selected driver is trustworthy."

Expected Flow

Home/Rides → Driver Verification

Observation

The participant was able to identify the driver's verification information and AI Safety Score. The verification indicators made it clear that the driver had passed several checks.

Result

Successful

Positive Feedback

The participant found the AI Safety Score useful because it provided a quick indication of the driver's safety level.

Task 3 – Track the Ride

Scenario

"You have selected your driver and your ride has started. Show where you would track the ride."

Expected Flow

Driver Verification → Live Tracking

Observation

The participant was able to recognize the Live Tracking screen through the map and driver information card.

The map clearly communicated the current ride location, while the driver card provided information about the driver and vehicle.

Result

Successful

Task 4 – Report an Emergency

Scenario

"Imagine that you feel unsafe during your ride. Show what you would do."

Expected Flow

Live Tracking → SOS → SOS Activating → Location Detected → SOS Activated

Observation

The SOS flow was understandable after the SOS button was made available on the Live Tracking screen.

However, during the initial version of the design, the Live Tracking screen did not contain a clearly accessible SOS action. This meant that the participant could not naturally start the emergency flow.

Result

Needs Improvement

Action Taken

The SOS button was added to the Live Tracking screen using the SOS component from the component library.

5. Usability Findings

Finding	Severity	Action
Main ride-booking flow was easy to understand	Low	No major change required
Driver verification information was clear	Low	Keep current structure
AI Safety Score was easy to identify	Low	Maintain consistent component
Live Tracking map was understandable	Low	Keep current layout
SOS was not initially available on Live Tracking	High	Add SOS button
SOS sequence needed clearer progression	Medium	Use separate SOS states
Different screens had some visual differences	Medium	Apply shared component library
Multiple actions on Live Tracking needed hierarchy	Medium	Make SOS and primary actions clearly distinguishable

6. Participant Feedback

Participant 1

Positive Feedback

- The login and ride-booking flow was easy to understand.
- Driver information was useful before selecting a driver.
- The AI Safety Score made the safety concept clear.

Suggested Improvement

The participant suggested making important safety actions more noticeable during an active ride.

Participant 2

Positive Feedback

- The Live Tracking map was easy to understand.
- The driver information card was useful.
- The SOS activation sequence clearly showed what was happening.

Suggested Improvement

The participant initially had difficulty identifying where to access the SOS feature because it was not clearly available in the original Live Tracking design.

7. Changes Made After Testing

Based on the usability testing, the following improvements were made or identified for implementation:

1. Added SOS to Live Tracking

The SOS button was added to the Live Tracking screen so that users can access emergency assistance while actively using the ride.

2. Improved SOS Flow

The emergency process was divided into clear stages:

SOS Activating → Location Detected → SOS Activated

This gives the user feedback about what the system is doing.

3. Standardized Components

The shared component library was used to improve consistency between screens.

The following components were standardized:

- Buttons
- Cards
- Badges
- AI Safety Score
- SOS Button
- Typography
- Colors
- Spacing

4. Improved Action Hierarchy

The Live Tracking screen was reviewed so that important actions are easier to distinguish from secondary actions such as calling, messaging, and sharing the trip.

8. Final Usability Evaluation

Overall, the SafeRide prototype successfully communicated the main user journey from authentication to ride tracking and demonstrated the emergency SOS concept.

The main usability issue identified during testing was the accessibility of the SOS feature from the Live Tracking screen. Adding a clearly accessible SOS button resolved the main navigation problem and allowed the SOS prototype flow to be connected naturally.

The testing also confirmed that the driver verification information and AI Safety Score successfully communicate SafeRide's primary focus on passenger safety.

Further refinement of spacing, visual consistency, and action hierarchy can improve the overall experience before final submission.

9. Conclusion

The usability testing helped identify practical issues that were not immediately obvious during the individual screen design process. Testing with two teammates provided feedback on navigation, information clarity, emergency actions, and visual consistency.

The feedback was used to improve the prototype and ensure that the final SafeRide experience provides a clear and safety-focused journey for users.

Final Prototype Flow:

Welcome → Login → Home/Rides → Driver Verification → Live Tracking → SOS → SOS Activating → Location Detected → SOS Activated
